

Objectives

- › Review ER & Golgi Complex
- › DNA replication
- › Mitosis
- › Meiosis

Functions of ER

- › Proteins to be secreted are made by ribosomes of rough ER
 - › Contain a **leader sequence** of 30+ hydrophobic amino acids that directs proteins to enter ER
 - › Inside ER leader sequence is removed; protein is modified

3-47

3-46

Functions of Golgi Complex

- › Secretory proteins leave ER in vesicles and go to Golgi Complex
 - › In Golgi complex carbohydrates are added to make glycoproteins
 - › Vesicles leave Golgi for lysosomes or exocytosis

3-47

Protein Degradation

- › Enzyme activity (& regulatory proteins) is controlled by degrading them:
 - › By **proteases** in lysosomes
 - › By **proteasomes** in cytoplasm
 - › Proteasomes (large enzyme complexes)
 - › **ubiquitin** tags mark proteins to be degraded

3-48

DNA Replication

- › Prior to cells dividing, DNA replicates itself and identical copies go to 2 daughter cells

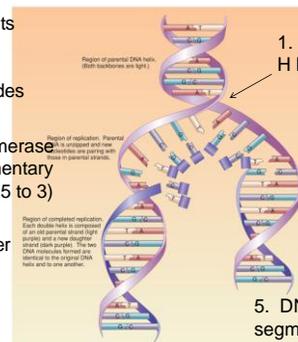

The Process of DNA replication:

- › **Helicase**: breaks hydrogen bonds to produce 2 free strands of DNA
- › **Primase**: established an RNA primer of RNA nucleotides
- › **DNA polymerase**: binds to each strand and makes new complementary copy of old strand
 - › Using A-T, C-G pairing rules
 - › Thus each copy is composed of 1 new strand and 1 old strand (called **semi-conservative replication**)
 - › Original DNA sequence is preserved

3-51

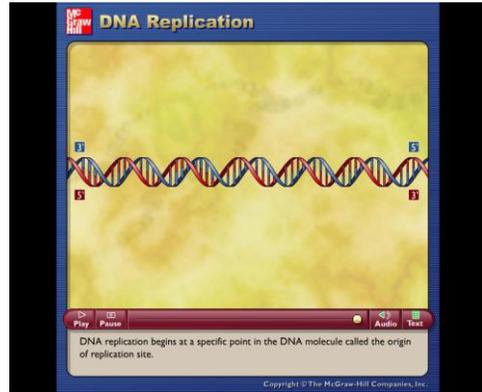

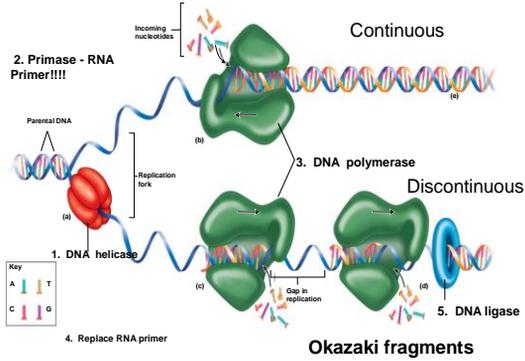

DNA Replication

2. Primase sets up short sequence of RNA nucleotides
3. DNA Polymerase adds complimentary Nucleotides (5 to 3)
4. RNA Primer is replaced with DNA nucleotides
5. DNA ligase joins segments together

3-52

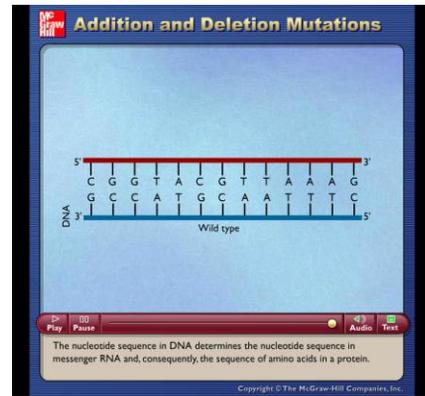

DNA Replication

Errors and Mutations

- ▶ DNA polymerase does make mistakes
 - ▶ But:
 - ▶ **tends** to replace incorrect, biochemically unstable pairs
 - thus, only 1 real error per 1 billion bases replicated
- ▶ DNA mutations: because of replication errors or environmental factors
 - ▶ some mutations = no problem/some big problem

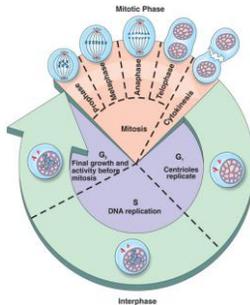

4-9

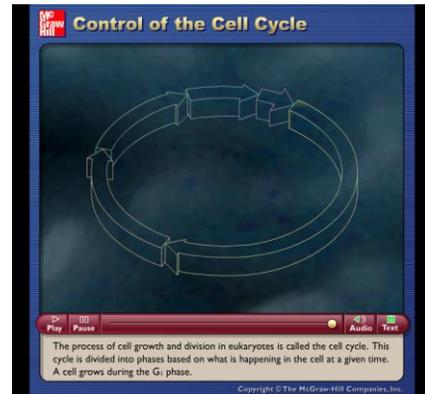

Cell Cycle

Most cells of body are in **interphase**, the non-dividing stage of life cycle

- ▶ Interphase is subdivided into:
 - ▶ **G₁** - cell performs normal physiological roles
 - ▶ **S** - DNA is replicated in preparation for division
 - ▶ **G₂** - chromatin condenses prior to division

3-55

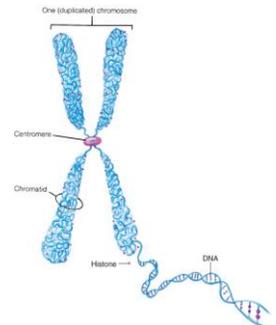

Mitosis

- ▶ Cell division occurs in all body cells (except eggs and sperm)
- ▶ Functions of mitosis:
 - ▶ growth of tissues
 - ▶ replacement of cells that die
 - ▶ repair of damaged tissues
- ▶ 4 phases of mitosis
 - ▶ prophase, metaphase, anaphase, telophase

4-13

Mitosis (M phase)

- ▶ When the cell divides
- ▶ Chromosome condense and duplicate
 - ▶ Consist of 2 duplicate strands called **chromatids**
 - ▶ connected by a **centromere**

3-59

Mitosis (M phase)

- ▶ In **prophase** chromosomes become visible distinct structures
- ▶ In **metaphase** chromosomes line up single file along equator
 - ▶ Positioned by **spindle fibers**
- ▶ In **anaphase** centromeres split
 - ▶ Spindle fibers pull each chromatid to opposite poles
- ▶ In **telophase** cytoplasm is divided (= **cytokinesis**), producing 2 daughter cells

3-61

Role of Centrosome

- ▶ Animal cells have a **centrosome** located near nucleus in interphase
 - ▶ Contains 2 centrioles

© D.M. Phillips / Visuals Unlimited

3-65

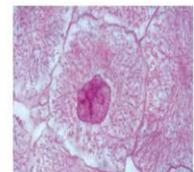

Role of Centrosome

- ▶ Centrosome is duplicated in G₁ if cell is going to divide
 - ▶ Replicates move to opposite poles by metaphase
 - ▶ Microtubules grow from centrosomes to form spindle fibers
 - attach to centromeres of chromosomes
 - ▶ Spindle fibers pull chromosomes to opposite poles during anaphase

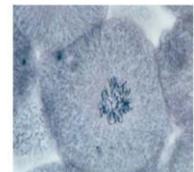

3-66

Mitosis (M phase)

- (a) Interphase
- The chromosomes are in an extended form and seen as chromatin in the electron microscope.
 - The nucleus is visible

- (b) Prophase
- The chromosomes are seen to consist of two chromatids joined by a centromere.
 - The centrosomes move apart toward opposite poles of the cell.
 - Spindle fibers are produced and extend from each centrosome.
 - The nuclear membrane starts to disappear.
 - The nucleolus is no longer visible.

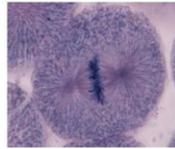

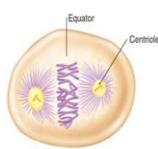

© Ed Pleschke

Mitosis

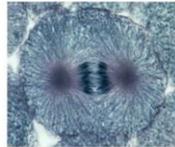

(c) Metaphase

- The chromosomes are lined up at the equator of the cell.
- The spindle fibers from each centriole are attached to the centromeres of the chromosomes.
- The nuclear membrane has disappeared.

(d) Anaphase

- The centromere split, and the sister chromatids separate as each is pulled to an opposite pole.

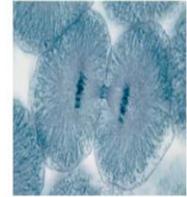

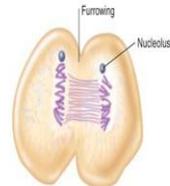

© Ed Reschke

3-63

Mitosis

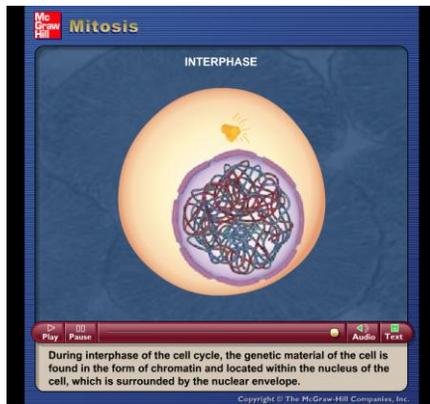

(e) Telophase

- The chromosomes become longer, thinner, and less distinct.
- New nuclear membranes form.
- The nucleolus reappears.
- Cell division is nearly complete.

© Ed Reschke

3-64

Telomeres

- ▶ Non-coding regions of DNA at ends of chromosomes
- ▶ Each time cell divides, a length of telomere is lost
 - ▶ Because DNA polymerase can't copy the very end of DNA strand
- ▶ When telomere is used up, cell becomes senescent
- ▶ Believed to represent a molecular clock for aging
 - That ticks down with each division
 - Trigger for apoptosis??

3-67

Telomeres

- ▶ Germinal and cancer cells can divide indefinitely and do not age
 - ▶ Have the enzyme **telomerase** which replaces telomere nucleotides not duplicated during DNA replication

3-68

Cyclins

- ▶ **Cyclins:** Proteins that promote different phases of cell cycle
 - ▶ Accumulate prior to mitosis
 - ▶ Destroyed during cell division
 - ▶ Promotes phases to occur and continue
- ▶ **Oncogenes:** genes whose mutations are associated with cancer
- ▶ **Tumor suppressor genes** inhibit cancer development
 - ▶ Tumor suppressor gene **p53** (transcription factor)
 - ▶ It halts cell division when DNA is damaged
 - ▶ Then either promotes repair of the DNA; or **apoptosis** (cell death)
 - ▶ Mutations in p53 are found in 50% of all cancers

3-56

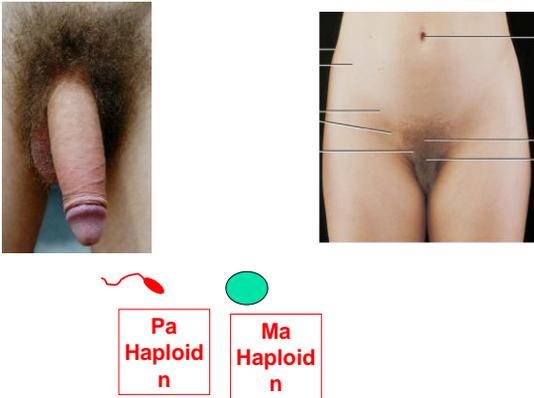

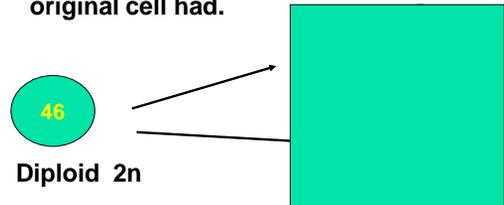

Cell Death

- ▶ Occurs in 2 ways:
 - ▶ **Necrosis**: pathological changes kill a cell
 - ▶ **Apoptosis**: normal physiological response
 - ▶ Extrinsic pathway – ligands bind to “death receptor proteins”
 - ▶ Intrinsic pathway – intracellular signals
 - ▶ Both pathways activate cytoplasmic caspases, which lead to cell death

3-58

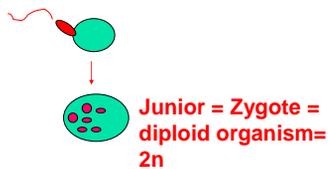

Meiosis

Meiosis: division of cells that results in daughter cells with one-half of the genetic information that the original cell had.

Meiosis

- ▶ Cell division occurring in ovaries and testes to produce gametes (ova and sperm)
- ▶ Two divisional sequences
- ▶ Daughter cells have ½ the chromosomes the original cell had

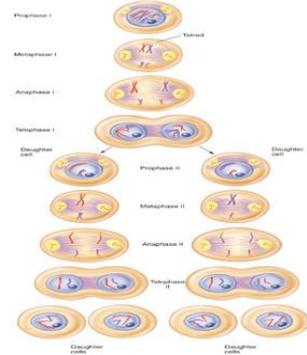

3-69

Meiosis

- ▶ **In 1st division:**
 - ▶ homologous chromosomes pair along equator of cell rather than singly as in mitosis
 - ▶ 1 member of homolog pair is pulled to each pole
 - ▶ gives each daughter cell 23 different chromosomes, consisting of 2 chromatids
- ▶ **In 2nd division:**
 - ▶ each daughter divides; chromosomes split into 2 chromatids
 - ▶ 1 goes to each new daughter cell
 - ▶ Each daughter cell contains 23 chromosomes
 - ▶ Original mother cell had 46
 - ▶ Aka reduction division

3-70

Meiosis

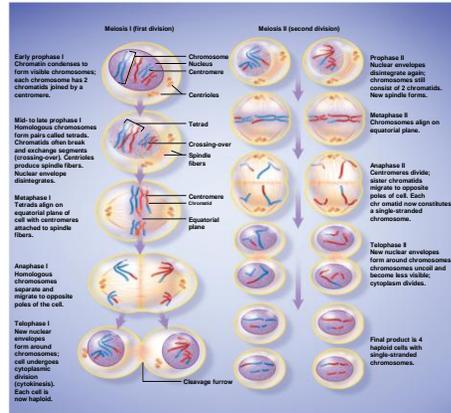

3-72

Genetic diversity & Meiosis

- ▶ Genetic recombination occurs in prophase I

1. **Crossing-over:** Parts of one homologous chromosome are exchanged with its partner homolog
2. **Independent assortment:** the way chromosomes line up during metaphase is random

3-73

How Meiosis Works

Male germ-line cell
Diploid (2n)

Female germ-line cell
Diploid (2n)

Meiosis is the process that results in the formation of sperm cells and egg cells. The cells that will undergo meiosis are typically found in the testes and ovaries of males and females respectively.

Meiosis with Crossing Over

Crossing over during meiosis allows recombination of genes between homologous chromosomes. This alters the linkage between genes on the same chromosome.

Spermatogenesis

- ▶ Germ cells that migrate from yolk sac during development become spermatogonia (stem cells)
- ▶ Spermatogonia replicate selves throughout life by mitosis
- ▶ Give rise to haploid sperm by meiosis

20-32

Oogenesis

Epigenetic Inheritance

- ▶ Occurs when gene silencing is passed on to daughter cells
 - ▶ Gene silencing is enacted by DNA methylation or post-translational modification of histones
- ▶ Can contribute to diseases
- ▶ Identical twins can have differences in gene expression
- ▶ --because of epigenetic changes in response to differences in their environments

3-74
